There are two primary routes for synthesizing alkyd resins:

- Polyesterification (Polycondensation) Method
- Interesterification and Modification

Each method influences the final resin's properties and application suitability.

- Polyesterification (Polycondensation) Method

This is the classical synthesis route, involving direct condensation of polyols and polyacids in the presence of catalysts such as acids or bases. The key steps include:

- Selection of raw materials: Fatty acids (or their derivatives), polyols, and polyacids
- Reaction conditions: Elevated temperatures (~200-250°C), often under inert atmosphere to prevent oxidation
- Catalysis: Acid catalysts such as p-toluenesulfonic acid (p-TSA) or basic catalysts like sodium or potassium catalysts

Reaction mechanism:

- The polyol's hydroxyl groups react with carboxylic acid groups from the polyacid, releasing water
- This condensation process continues, building long-chain polyester molecules with ester linkages
- Incorporation of fatty acids introduces hydrophobic tails, influencing drying and hardness

Critical parameters:

- Temperature control: To prevent premature gelation or degradation
- Molar ratios: Precise stoichiometry ensures desired molecular weight and properties
